**Abstract**—A new combination reagent of CaH<sub>2</sub>/ZnX<sub>2</sub> effectively reduced a variety of ketones and imines to the corresponding alcohols and amines, respectively, in the presence of a catalytic amount of a Lewis acid such as Ti(O-*i*-Pr)<sub>4</sub>, Al(O-*i*-Pr)<sub>3</sub>, B(O-*i*-Pr)<sub>3</sub> and ZnF<sub>2</sub>.  $\bigcirc$  2011 Elsevier Science. Reduction with metal hydride reagents has been widely utilized as a routine protocol in organic synthesis, and numerous hydride compounds and reagent systems have been developed and are used. Recently, efforts have been made to utilize LiH as a hydride source, which is a basically inert metal hydride, inexpensive, stable to handle and environmentally benign. Thus, in 1994 Noyori et al. demonstrated that LiH could be used as an agent for carbonyl reduction in the presence of TMSCl and a catalytic amount of ZnX<sub>2</sub>.<sup>1</sup> At the same time, Sato et al. showed that reaction of alkynes or conjugated dienes with ZnI<sub>2</sub>/2LiH reagent underwent hydrometalation in the presence of Cp2TiCl2.2 Generation of dialkylzinc hydride ate complexes from LiH and ZnR<sub>2</sub> has been also reported.<sup>3</sup> These results prompted us to investigate use of CaH<sub>2</sub> as a reductive hydride source, which is also a basically inert, inexpensive, and stable metal hydride and is usually used as a drying agent. Herein we report that a reagent combination of CaH<sub>2</sub> and ZnX<sub>2</sub> reduces effectively ketones and imines to the corresponding alcohols and amines in the presence of a catalytic amount of a Lewis acid.

To investigate the possibility of the use of CaH<sub>2</sub> as a reductive hydride source, we carried out the reactions of acetophenone (**1a**) and an imine **2a** derived from benzaldehyde and benzyl amine with CaH<sub>2</sub> and ZnX<sub>2</sub> under various reaction conditions (Table 1).<sup>4,5</sup> Thus, a mixture of CaH<sub>2</sub> (powder, 1.3 mmol) and anhydrous ZnX<sub>2</sub> (0.2~1.4

The resulting mixture was stirred for 12 h at room temperature or 40  $^{\circ}$ C.

As revealed from Table 1, it was found that  $CaH_2$  could act as a reductive hydride source: With a 1.3:1.4 mixture of  $CaH_2$  and  $ZnBr_2$ , a trace amount of **3a** was obtained by the reaction of **1a** (entry 1) and imine **2a** was effectively reduced to amine **4a** (entry 9). However, a 1.3:1.2 mixture of  $CaH_2$  and  $ZnBr_2$  did not reduce **1a** and **2a** at all (entries 2 and 10).  $CaH_2$  in the presence of a catalytic amount of  $ZnBr_2$  and a stoichiometric amount of TMSCl reduced **1a** in THF; however, the reaction did not complete (entry 3). We found that in the presence of a catalytic amount of  $Ti(O-i-Pr)_4$  an essentially inert 1.3:1.2 mixture of  $CaH_2$  and  $ZnX_2$  could reduce **1a** and **2a** quantitatively to afford **3a** and **4a**, respectively (entries 5-7 and 11), where  $ZnCl_2$ ,  $ZnBr_2$ ,  $ZnI_2$  could be used equally. However, the reaction with  $ZnF_2$  did not proceed at all (entry 8).

With these results, we studied the stoichiometry of  $CaH_2$ and  $ZnX_2$  in the reaction. As can be seen from eq 1, it was found that the reduction was stoichiometric on both  $CaH_2$ and  $ZnX_2$ : thus, a 2:1 and 1:1 mixture of  $CaH_2$  and  $ZnBr_2$ reduced **1a** in a stoichiometric fashion to the amount of ZnBr<sub>2</sub>. However, a 1:2 mixture of  $CaH_2$  and ZnBr<sub>2</sub> was nearly inert.

The results shown in Table 1 and eq 1 may be explained by the following assumptions: (i)  $CaH_2$  and  $ZnX_2$  except for  $ZnF_2$  can make a complex(es) in a 1:1 ratio when one or more equivalent of  $CaH_2$  was mixed with  $ZnX_2$ . A 1:2 mixture of  $CaH_2$  and  $ZnX_2$  may make a different species. (ii) A 1:1 complex(es) of  $CaH_2$  and  $ZnX_2$  thus generated is essentially inert for reduction of ketones and imines. Ti(O*i*-Pr)<sub>4</sub> may act as a Lewis acid activating the substrates in a catalytic manner to undergo the reduction with a  $CaH_2/ZnX_2$  (1:1) reagent.<sup>6</sup>

Based on these hypotheses we carried out the reaction with other Lewis acid catalysts (Table 2). As expected, in addition to Ti(O-*i*-Pr)<sub>4</sub> other metal alkoxides (5 mol%) such as Al(O-*i*-Pr)<sub>3</sub> and B(O-*i*-Pr)<sub>3</sub> could effectively catalyze the reduction of **1a** and **2a** with CaH<sub>2</sub>/ZnBr<sub>2</sub> (1.3:1.2). Similarly, ZnF<sub>2</sub> catalyzed the reduction of ketone and imine (entries 4 and 8).<sup>6</sup>

With these results in hand, we chose a reagent system  $CaH_2/ZnBr_2/Ti(O-i-Pr)_4$  (1.3:1.2:0.05) and carried out the reduction of other ketones and imines.<sup>7</sup> The results of the reactions with the representative carbonyl compounds and imines are summarized in Table 3 and Table 4, respectively.

<sup>a</sup> Isolated yield unless otherwise indecated. <sup>b</sup>Zn Cl<sub>2</sub> was used instead of Zn Br<sub>2</sub>. <sup>c</sup>Determined by <sup>1</sup>H NMR analysis of the crude residue using an internal standard. <sup>d</sup>62% of 1 was recovered.

As revealed from Table 3, diaryl and aryl alkyl ketones and cyclic ketones could be effectively reduced. Aldehydes and acyclic aliphatic ketones, however, were not good substrates. As shown in entries 1 and 5, ZnCl<sub>2</sub> as well as ZnBr<sub>2</sub> could be equally used for the reduction.

The reduction of benzil by the present method provided meso-hydrobenzoin exclusively (eq 2). The stereoselectivity can be explained by considering the

chelation control mechanism similar to that proposed for the reduction with other metal hydrides.

As listed in Table 4, a  $CaH_2/ZnX_2/Ti(O-i-Pr)_4$ (1.3:1.2:0.05) reagent could reduce a variety of imines in excellent yields. Thus, imines derived from aromatic and aliphatic aldehydes were cleanly converted to the corresponding amines. Imines having a benzyl, alkyl, or aromatic group as an *N*-substituent were good substrates. Functional groups such as bromo and alkenyl moieties present in the substrate were tolerant as shown in entries 4 and 6. Ketimine was also reduced in excellent yield (entry 8). ZnCl<sub>2</sub> was again found to be equally effective as ZnBr<sub>2</sub> (entries 1 and 3).

<sup>a</sup>lsolated yield. <sup>b</sup>Zn Cl<sub>2</sub> was used instead of Zn Br<sub>2</sub>.

In summary, herein we have reported that  $CaH_2$  could be used as a reductive hydride source together with  $ZnX_2$  and a catalytic amount of a Lewis acid, the reagent system of which could perform the reduction of ketones and imines to the corresponding alcohols and amines in good yield. To our knowledge, this is the first example of a  $CaH_2$ -based reduction of organic molecules except for those through boron hydride formation and reduction of sulfate to sulfide.<sup>8,9</sup>

- 4. CaH<sub>2</sub> (powder), anhydrous ZnCl<sub>2</sub>, ZnBr<sub>2</sub>, ZnI<sub>2</sub> and ZnF<sub>2</sub> were purchased from Wako Pure Chemical Industries, Ltd.
- Under similar conditions the reaction of CaH<sub>2</sub> with MgBr<sub>2</sub> in the presence or absence of Ti(O-*i*-Pr)<sub>4</sub> did not reduce 1a at all.
- 6. Although formation of metal hydrides derived from Ti(O-*i*-Pr)<sub>4</sub>, B(O-*i*-Pr)<sub>3</sub> or Al(O-*i*-Pr)<sub>3</sub> can not be ruled out, the fact that ZnF<sub>2</sub>, which was inert in the presence of Ti(O-*i*-Pr)<sub>4</sub>, was an effective catalyst as well as Ti(O-*i*-Pr)<sub>4</sub> and activated the reaction with CaH<sub>2</sub>/ZnBr<sub>2</sub> (1.3:1.2) may suggest a role of these metal alkoxide as a Lewis acid. In addition, the reaction of **1a** and CaH<sub>2</sub> (1.3 eq.) with 1.3 equiv of Ti(O-*i*-Pr)<sub>4</sub>, B(O-*i*-Pr)<sub>3</sub> or Al(O-*i*-Pr)<sub>3</sub> in the absence of ZnX<sub>2</sub> did not proceed at all.
- 7. General procedure: A suspension of CaH<sub>2</sub> (1.3 mmol) and ZnX<sub>2</sub> (1.2 mmol) in THF (3 mL) was stirred for 1.5 h at 40 °C. To this were added a solution of ketone or imine (1.0 mmol) in THF (1 mL) and Lewis acid (0.05 mmol). The resulting mixture was stirred for 12 h at 40 °C. After being cooled to room temperature, the mixture was slowly poured into aqueous saturated NH<sub>4</sub>Cl. The mixture was extracted with ether or AcOEt, dried over MgSO<sub>4</sub> and concentrated.
- It has been reported that CaH<sub>2</sub> and B(OMe)<sub>3</sub> gave a complex at 215 °C, which reduced carbonyl compounds: Hesse, Gerhard; Jager, Horst, *Chem. Ber.* **1959**, *92* 2022.
